Making Decisions under Model Misspecification

Simone Cerreia-Vioglio, Lars Peter Hansen, Fabio Maccheroni, Massimo Marinacci

TD III 1 luglio 2021, Università di Parma

Probability of facts and of theories

Probability of facts and of theories

- Decisions' consequences depend on external factors (contingencies)
- Probability of contingencies
- Probabilistic theories on contingencies (e.g., generative mechanisms, DGP)
- Thinking over such theories
- Environments with uncertainty through the guise of models (e.g., policy making)
- Decision making under model uncertainty

Savage Decision problems

Savage Decision problems

A decision problem consists of

- a space \mathcal{F} of acts $f: S \to C$
- a space *C* of material (e.g., monetary) consequences
- a space S of environment states
- The quartet (F, S, C, ≿) is a Savage decision problem under uncertainty
- If C is a convex subset of a vector space, this quartet takes the Anscombe-Aumann form

 We abstract from state misspecification issues (e.g., unforeseen contingencies) Probability models

Probability models

- Δ is the set of probability measures on S
- DMs posit a set Q of *structured* (probability) *models* $q \in \Delta$ on states, with a substantive motivation or scientific underpinnings
- Each q describes a possible DGP, so it represents physical uncertainty (risk)

Probability models

Probability models

- DMs thus posit a model space Q in addition to the state space S
- When the model space is based on experts' advice, its nonsingleton nature may reflect different advice
- Denti and Pomatto (2019) came up with a behavioral counterpart of Q
- To ease matters, Q is a convex and compact subset of Δ^{σ}

Uncertainty: a taxonomy

Uncertainty: a taxonomy

- The quintet (F, S, C, Q, ≿) forms a classical decision problem under uncertainty
- If DMs know that the correct model belongs to Q, they confront model ambiguity (or uncertainty)
- If DMs know the correct model within Q, they confront *risk*

Uncertainty: a taxonomy

Uncertainty: a taxonomy

In this setup, we can decompose uncertainty in three distinct layers:

- (Model) risk: uncertainty within a model q
- Model ambiguity or uncertainty: uncertainty across models in Q
- Model misspecification: uncertainty about models (the correct model does not belong to the posited set Q)

(日) (同) (三) (三) (三) (○) (○)

Model misspecification: Relevance

Model misspecification: Relevance

- Do data reveal DGPs and so speak, by and large, for themselves?
- If so, model misspecification is a minor issue
- Is theoretical reasoning needed to interpret empirical phenomena?

If so, model misspecification is a major issue

Model misspecification: Issues

Model misspecification: Issues

- There is no decision criterion that accounts for model misspecification concerns
- Models with agents confronting model misspecification are unable to address agents' misspecification concerns (they even use expected utility preferences)

Model misspecification

Model misspecification

- Suppose that DMs confront model misspecification
- At the time of decision, they are afraid that none of the posited structured models is correct

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Model misspecification (Hansen and Sargent, 2020)

Model misspecification (Hansen and Sargent, 2020)

• The DM contemplates also *unstructured models* $p \in \Delta$ in ranking actions according, for example, to a conservative decision criterion

$$V(f) = \min_{p \in \Delta} \left\{ \int u(f) \, dp + \lambda \min_{q \in Q} R(p||q) \right\}$$

- $\lambda > 0$ is an index of misspecification fear
- The relative entropy $R(\cdot || \cdot)$ is an index of statistical distance between models (structured or not)
- So, $\min_{q \in Q} R(p||q)$ is an Hausdorff "distance" between p and Q

└─A protective belt

A protective belt

 Unstructured models lack the substantive status of structured models, they are essentially statistical artifacts

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

In this variational criterion, they act as a protective belt against model misspecification Model ambiguity: back to Wald 1950

Model ambiguity: back to Wald 1950

- The higher λ is, the lower the misspecification fear is
- If $\lambda = +\infty$, the criterion takes a maxmin form

$$V(f) = \min_{q \in Q} \int u(f) \, dq$$

and we are back to model ambiguity

- Without misspecification fear, the DM would maxminimize over structured models
- No prior beliefs (cf. general maxmin analysis of Gilboa and Schmeidler, 1989)

 If Q is a singleton {q}, so no model ambiguity, we have the multiplier criterion

$$V(f) = \min_{p \in \Delta} \left\{ \int u(f) \, dp + \lambda R(p||q) \right\}$$

 Under the protective belt interpretation, it is the criterion of an expected utility DM who fears model misspecification (about the unique posited model)

General form

General form

In general, a decision criterion under model misspecification is

$$V(f) = \min_{p \in \Delta} \left\{ \int u(f) \, dp + \min_{q \in Q} c(p, q) \right\}$$

- Here $c : \Delta \times Q \rightarrow [0, \infty]$ is a statistical distance (for the set Q), with c (p, q) = 0 iff q = p
- E.g., the relative entropy $R(\cdot || \cdot)$ or, more generally, a Csiszar ϕ -divergence $D_{\phi}(\cdot || \cdot)$

• We have $\min_{q \in Q} c(p||q) > 0$ iff $p \notin Q$

Box and all that

- Structured models may be incorrect, yet useful as Box (1979) famously remarked
- Formally, betting behavior must be *consistent* with datum Q, i.e.,

$$q\left(F
ight)\geq q\left(E
ight) \quad orall q\in Q \Longrightarrow$$
 "bet on F " \succsim "bet on E "

Under bet-consistency, a DM may fear model misspecification yet regards structured models as good enough to choose to bet on events that they unanimously rank as more likely Mild model misspecification

Mild model misspecification

- A mild form of fear of model misspecification
- **PROP** The decision criterion

$$V\left(f
ight)=\min_{p\in\Delta}\left\{\int u\left(f
ight)dp+\lambda\min_{q\in Q}R(p||q)
ight\}$$

is bet-consistent

• The result continues to hold for any ϕ -divergence $D_{\phi}(p||q)$

Misspecification neutrality

Misspecification neutrality

• A preference \succeq is *misspecification neutral* if

$$\int u(f) dq \geq \int u(g) dq \quad \forall q \in Q \Longrightarrow f \succeq g$$

for all acts f and g

- In this case, for decision-theoretic purposes fear of misspecification plays no role
- We are back to aversion to model ambiguity

Misspecification neutrality

Misspecification neutrality

PROP A preference \succeq represented by the decision criterion

$$V(f) = \min_{p \in \Delta} \left\{ \int u(f) \, dp + \min_{q \in Q} c(p, q) \right\}$$

is misspecification neutral iff it is represented by the maxmin criterion

$$V(f) = \min_{q \in Q} \int u(f) \, dq$$

 This confirms behaviorally that the maxmin criterion corresponds to aversion to model ambiguity, with no fear of misspecification. A tale of two preferences

A tale of two preferences

- We axiomatize this criterion within a two-preference setup a la Gilboa et al. (2010), in an Anscombe-Aumann setting
- A dominance relation ≿* represents the DM "genuine" preference on acts, so it is typically incomplete
- A behavioral preference ≿ governs choice, so it is complete (burden of choice)

Rational preference

Rational preference

- A.1 A preference \succeq is (subjectively) rational if it is:
- (a) complete
- (b) risk independent: if $x, y, z \in X$ and $\alpha \in (0, 1)$, then $x \sim y$ implies $\alpha x + (1 \alpha) z \sim \alpha y + (1 \alpha) z$
 - Risk independence implies that ≿ on X (e.g., on lotteries) is represented by an affine (e.g., expected) utility function
 u : X → ℝ

Dominance relation

Dominance relation

A.2 A preference \succeq^* on \mathcal{F} is a *dominance relation* (or is *objectively rational*) if it is:

(a) c-complete: if $x, y \in X$, then $x \succeq^* y$ or $y \succeq^* x$

(b) completess: when Q is a singleton, $f \succeq^* g$ or $g \succeq^* f$ for all $f, g \in \mathcal{F}$

(c) weak c-independent: if $f, g \in \mathcal{F}$, $x, y \in X$, and $\alpha \in (0, 1)$,

 $\alpha f + (1-\alpha) x \succsim^* \alpha g + (1-\alpha) x \Rightarrow \alpha f + (1-\alpha) y \succsim^* \alpha g + (1-\alpha) y$

(d) convex: if $f, g, h \in \mathcal{F}$ and $\alpha \in (0, 1)$,

$$f \succeq^* h \text{ and } g \succeq^* h \Rightarrow \alpha f + (1 - \alpha) g \succeq^* h$$

Dominance relation

Dominance relation

- Model ambiguity (i.e., a nonsingleton Q) underlies the incompleteness of ≿*

A.3 Preferences \succeq^* and \succeq are *consistent* if

$$f \succeq^* g \Longrightarrow f \succeq g$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

for all $f, g \in \mathcal{F}$

Caution

Caution

• A.4 Preferences
$$\succeq^*$$
 and \succeq satisfy *caution* if

$$f \not\gtrsim^* x \Longrightarrow x \succeq f$$

for all $x \in X$ and all $f \in \mathcal{F}$

 DM opts, by default, for a sure alternative x over an uncertain one f, unless the dominance relation says otherwise

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

└─Q-Coherent (objective)

Q-Coherent (objective)

• We write
$$f \stackrel{Q}{=} g$$
 when $q (f = g) = 1$ for all $q \in Q$

■ A.5 A dominance relation ≿* on F is (objectively) Q-coherent if

$$f \stackrel{Q}{=} g \implies f \sim^* g$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

└─Q-Coherent (subjective)

Q-Coherent (subjective)

Given a model p ∈ ∆, define a consequence x^p_f ∈ X for each act f via the equality

$$u(x_{f}^{p})=\int u\left(f
ight) dp$$

We can interpret x^p_f as the "certainty" equivalent of act f if p were the correct model

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Q-Coherent (subjective)

Q-Coherent (subjective)

■ **A.6** A rational preference \succeq is (*subjectively*) *Q*-coherent if, for all $f \in \mathcal{F}$ and all $x \in X$, we have

$$x \succ^* x_f^p \Longrightarrow x \succ f$$

if and only if $p \in Q$

A probability p is a structural model when DMs take it seriously, i.e., they never choose acts that would be strictly dominated if p were correct

Divergences

Given a (non-empty) subset Q of Δ , a function $c : \Delta \times Q \rightarrow [0, \infty]$ is a *divergence* (for the set Q) if

- (i) the sections $c_q:\Delta\to [0,\infty]$ are grounded, lsc and convex for each $q\in Q$
- (ii) the function $c_Q : \Delta \to [0, \infty]$ defined by

$$c_{Q}\left(p
ight)=\min_{q\in Q}c\left(\cdot,q
ight)$$

is well defined, grounded, lsc and convex (iii) $c_Q^{-1}(0) = Q$, that is, $c_Q(p) = 0$ if and only if $p \in Q$ └─Statistical distances

Statistical distances

A divergence c that satisfies the distance property

$$c(p,q) = 0 \Longleftrightarrow p = q$$

is called statistical distance

• $c_Q(p)$ is now an Hausdoff-type statistical distance between p and Q

THM Let $(S, \Sigma, X, Q, \succeq^*, \succeq)$ be a two-preference classical decision environment. The following statements are equivalent:

(i) \succeq^* is a unbdd dominance relation and \succeq is a rational preference that are both *Q*-coherent and jointly satisfy consistency and caution;

(ii) there exist an onto affine function $u: X \to \mathbb{R}$ and a divergence $c: \Delta \times Q \to [0, \infty]$, with dom $c_Q \subseteq \Delta(Q)$, such that, for all acts $f, g \in \mathcal{F}$,

$$f \succeq^* g \Leftrightarrow \min_{p \in \Delta} \left[\int u(f) \, dp + c \, (p, q) \right] \ge \min_{p \in \Delta} \left[\int u(g) \, dp + c \, (p, q) \right]$$

for all $q \in Q$, and

$$f \succeq g \Leftrightarrow \min_{p \in \Delta} \left[\int u(f) \, dp + \min_{q \in Q} c(p, q) \right] \ge \min_{p \in \Delta} \left[\int u(g) \, dp + \min_{q \in Q} c(p, q) \right]$$

If, in addition, c is uniquely null, then $c : \Delta \times Q \rightarrow [0, \infty]$ can be chosen to be a statistical distance.

 This result identifies the main preferential assumptions underlying a representation

$$V(f) = \min_{p \in \Delta} \left\{ \int u(f) \, dp + \min_{q \in Q} c(p, q) \right\}$$

where $c:\Delta\times Q\rightarrow [0,\infty]$ is a statistical distance

• Let \succeq_1 be \succeq_2 represented by this criterion with same u

• \succeq_1 is more uncertainty averse than \succeq_2 iff

$$\min_{q \in Q} c_1(\cdot, q) \leq \min_{q \in Q} c_2(\cdot, q)$$

The function

$$p\mapsto\min_{q\in Q}c\left(p,q
ight)$$

as an index of aversion to model misspecification, for short, a *misspecification index*

 The lower is this index, the higher is the fear of misspecification

Varying structured information

- So far, a given set Q of structured models
- We should write

$$(S, \Sigma, X, \succeq^*_Q, \succeq_Q)$$

with the dependence of preferences on Q highlighted

- Yet, decision environments may share common state and consequence spaces, but differ on the posited sets of structured models because of different information that DMs may have
- Need of decision criteria that, across such environments, are consistent

Varying structured information

• Let ${\mathcal Q}$ be the family of convex and compact subsets of Δ^σ

Consider a family

$$\{(S, \Sigma, X, \succeq_Q^*, \succeq_Q)\}_{Q \in Q}$$

of decision environments that differ in the set Q of posited models

Introduce axioms that connect these environments

Varying structured information

A.7 The family $\{\succeq_Q^*\}_{Q \in Q}$ is monotone (in model ambiguity) if $Q' \subseteq Q$ implies, for all $f, g \in \mathcal{F}$,

$$f \succsim^*_Q g \Longrightarrow f \succsim^*_{Q'} g$$

- If the "structured" information underlying a set Q is good enough for the DM to establish that an act dominates another one, a better information which decreases model ambiguity can only confirm such judgement
- Its reversal would be at variance with the objective rationality spirit of the dominance relation

Varying structured information

A.8 The family $\{\succeq_Q^*\}_{Q \in Q}$ is *Q*-separable if, for each $f, g \in \mathcal{F}$ and $x \in X$,

$$\forall q \in Q, f \succeq^*_q g \implies f \succeq^*_Q g$$

- If, without model ambiguity, an act unanimously dominates another one according to each model q in Q, so does under model ambiguity when Q is the set of structured models
- No model in Q supports a reversal of this dominance judgement

Varying structured information

• Previous axioms imply that \succeq_Q^* agree on X

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

• We thus just write \succeq^*

Varying structured information

Denote by $x_{f,q}$ the certainty equivalent of act f for preference \gtrsim_q^*

A.7 Model hybridization aversion. Given any $q, q' \in \Delta^{\sigma}$,

$$\lambda x_{f,q} + (1-\lambda) x_{f,q'} \succeq^* x_{f,\lambda q+(1-\lambda)q'}$$

for all $\lambda \in (0, 1)$ and all $f \in \mathcal{F}$

• DM dislikes, *ceteris paribus*, facing a hybrid structured model $\lambda q + (1 - \lambda) q'$ that, by mixing two structured models q and q', could only have a less substantive motivation

Varying structured information

THM Let

$$\{(S, \Sigma, X, \succeq_Q^*, \succeq_Q)\}_{Q \in Q}$$

be a family of two-preference classical decision environments. The following statements are equivalent:

(i) $\{\succeq_Q^*\}_{Q \in \mathcal{Q}}$ is monotone, *Q*-separable and, for each $Q \in \mathcal{Q}$, the preferences \succeq_Q^* and \succeq_Q satisfy the hypotheses of Theorem 1;

Varying structured information

(ii) there exist an onto affine function $u: X \to \mathbb{R}$ and a lsc and convex statistical distance $c: \Delta \times \Delta^{\sigma} \to [0, \infty]$, with dom $c_Q \subseteq \Delta(Q)$ for each $Q \in Q$, such that, for all acts $f, g \in \mathcal{F}$,

$$f \succeq_{Q}^{*} g \Leftrightarrow \min_{p \in \Delta} \left[\int u(f) \, dp + c(p,q) \right] \geq \min_{p \in \Delta} \left[\int u(g) \, dp + c(p,q) \right]$$

for all $q \in Q$, and

$$f \succeq_{Q} g \Leftrightarrow \min_{p \in \Delta} \left[\int u(f) dp + \min_{q \in Q} c(p,q) \right] \ge \min_{p \in \Delta} \left[\int u(g) dp + \min_{q \in Q} c(p,q) \right]$$

Moreover, u is unique up to a positive affine transformation and, given u, c is unique
